D. Rossi  
dario.rossi@enst.fr

- This talk about:
  - Operational costs of ISPs
  - Reduction through caching
  - Information Centric Networks
- Our contribution
  - Classic caching is cost-ineffective
  - Optimal caching for ISP cost reduction (in theory)
  - Cost-aware cache policy (real implementation)

- Efficient bandwidth usage
- Reduced network load
- Reduced delay
- Better QoE

*“Money plays the largest part in determining the course of history”*

Karl Marx

Can caching in ICN  
reduce ISP operational  
costs?

# ISP network

---

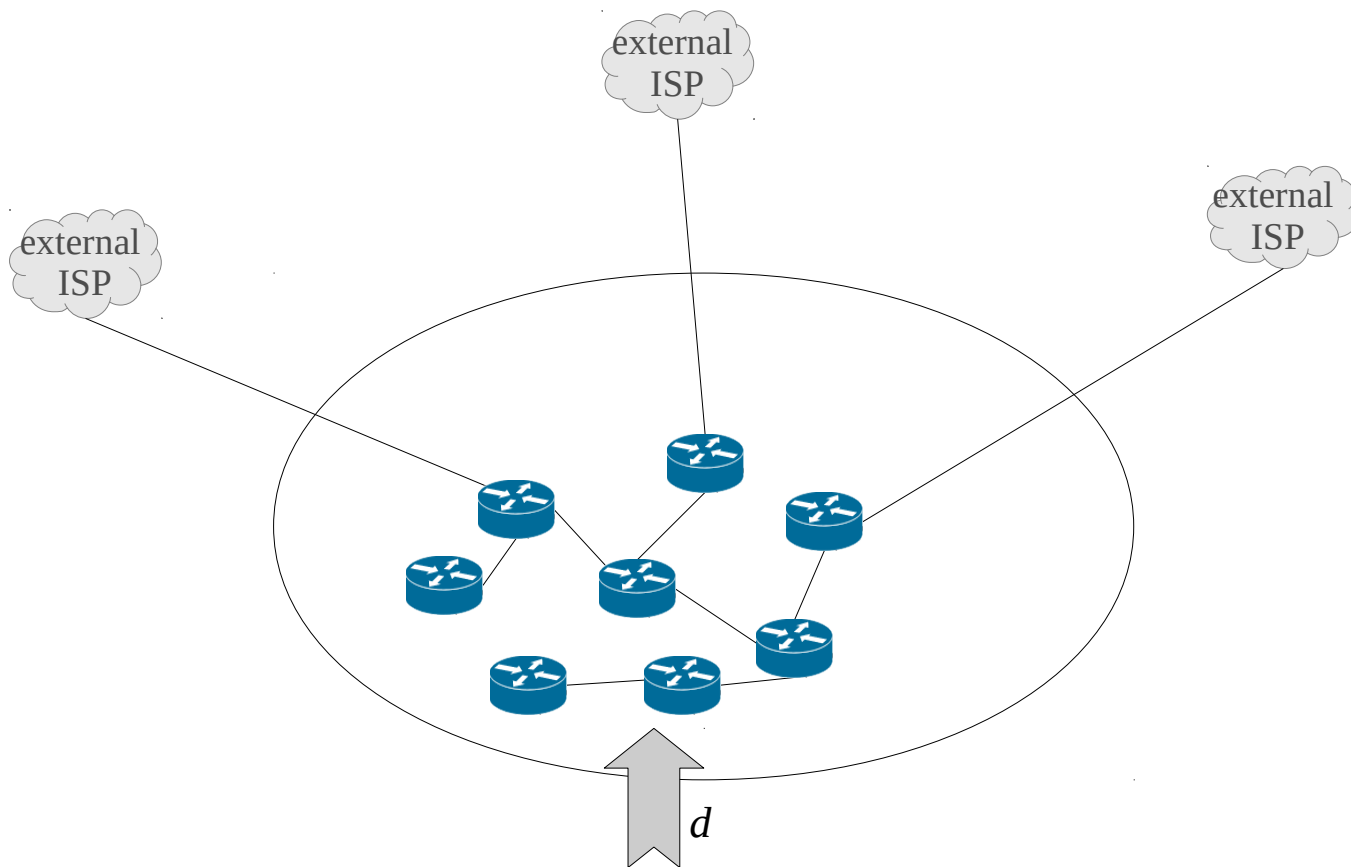

---

# ISP network

---

---

# ISP network

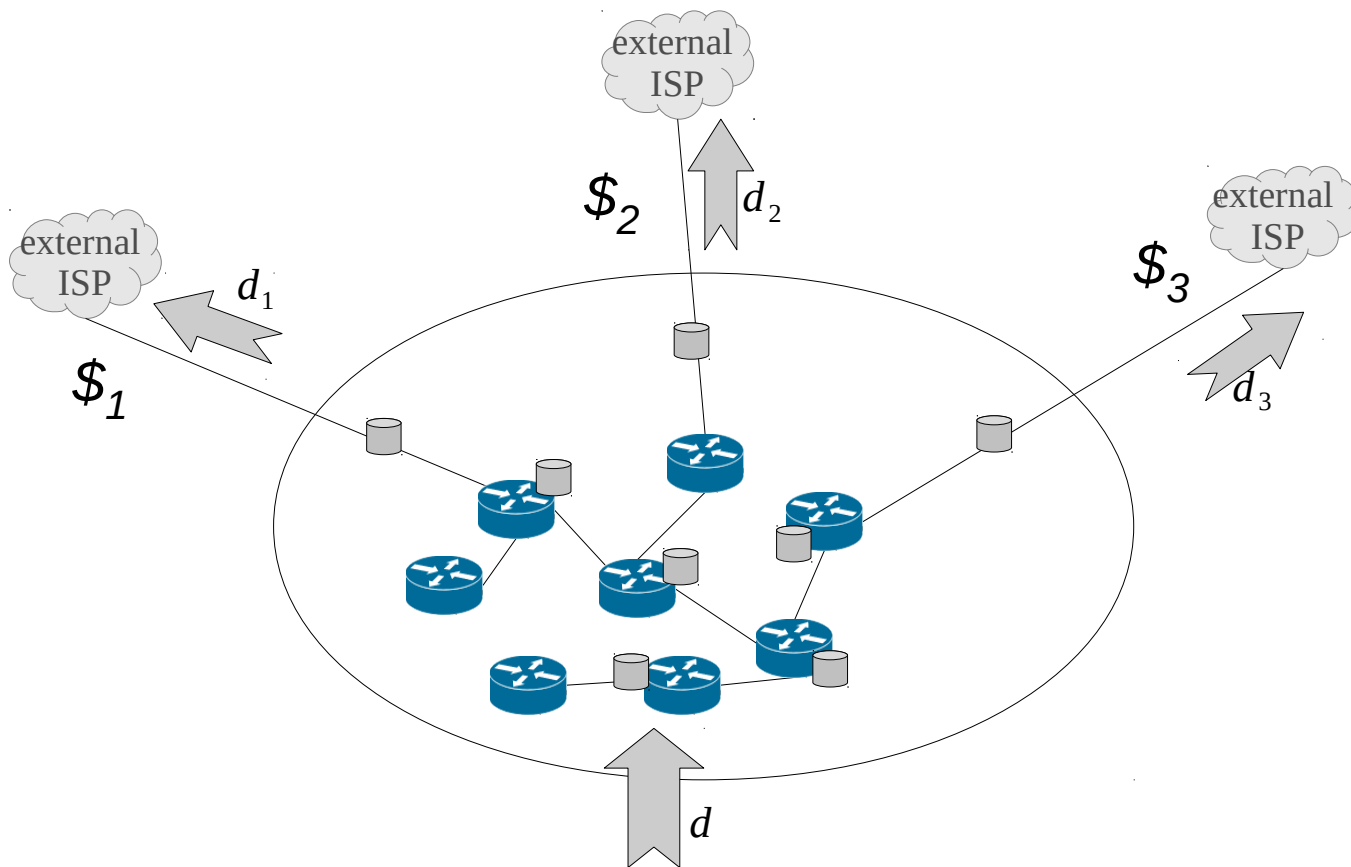

# ISP network

$$\text{Cost: } C = \sum_i d_i \$i$$

# ISP network

$$\text{Cost: } C = \sum_i d_i \$i$$

$$\$1 < \$2 < \$3$$

# ISP network

$$\text{Cost: } C = \sum_i d_i \$i$$

# ISP network

$$\text{Hit ratio: } H = \frac{d - \sum_i d_i}{d}$$

$$\text{Cost: } C = \sum_i d_i \$i$$

Classic caching: max  $H$

# ISP network

$$\text{Hit ratio: } H = \frac{d - \sum_i d_i}{d}$$

$$\text{Cost: } C = \sum_i d_i \$i$$

Classic caching: max  $H$

$$\boxed{\text{max } H \Rightarrow \text{min } C}$$

(cost)

$$\$1 < \$2 < \$3$$

# ISP network

$$\text{Hit ratio: } H = \frac{d - \sum_i d_i}{d}$$

$$\text{Cost: } C = \sum_i d_i \$i$$

Classic caching: max  $H$

H, C are conflicting goals

Price heterogeneity

$$\$1 < \$2 < \$3$$

# Optimization model

Hit ratio:  $H = \frac{d - \sum_i d_i}{d}$

Cost:  $C = \sum_i d_i s_i$

Classic caching: MAX-HIT

vs.

Cost-aware caching: MIN-COST

We find the optimal

- object placement
- cache sizing
- forwarding

# Greedy algorithms

---

---

## MAX-HIT (classic)

- Cache the  $|C|$  objects with the highest number of requests  $d^o$

cache size

## MIN-COST (cost-aware)

- Cache the  $|C|$  objects with the highest cost  $d^o \cdot \$o$

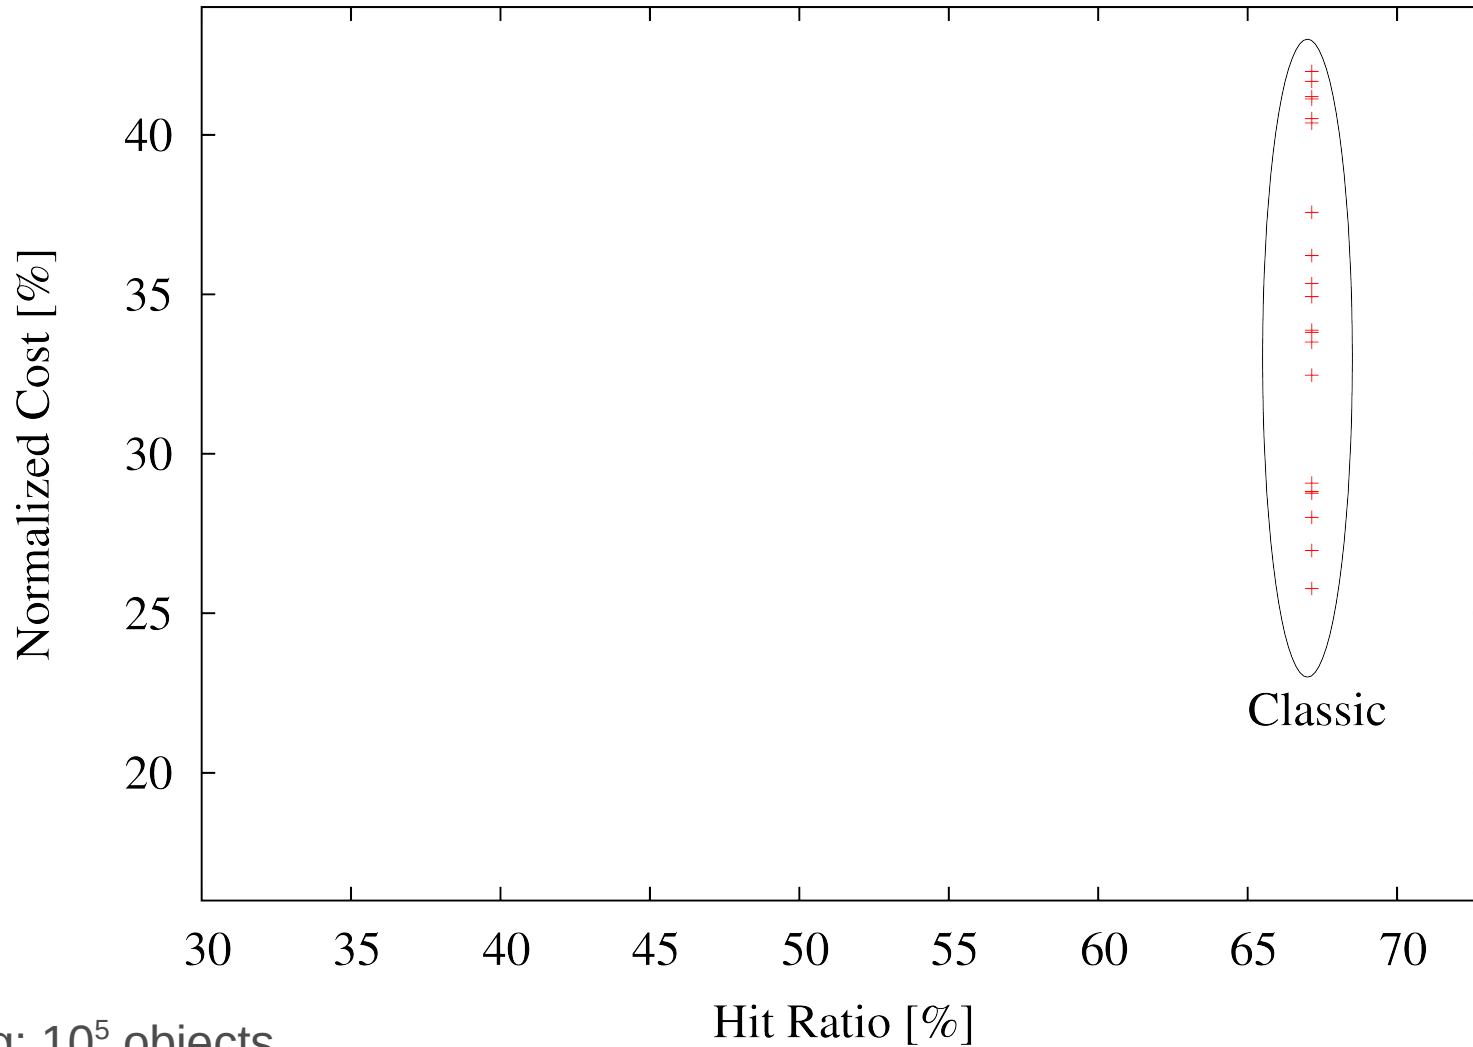

Price of the link giving access to object  $o$

Polynomial time

# Hit-ratio vs. cost tradeoff

Catalog:  $10^5$  objects

Cache:  $10^3$  objects

Zipf exponent: 1

Prices:  $(\$_1, \$_2, \$_3) = (0, 1, 10)$

# Hit-ratio vs. cost tradeoff

Catalog:  $10^5$  objects

Cache:  $10^3$  objects

Zipf exponent: 1

Prices:  $(\$_1, \$_2, \$_3) = (0, 1, 10)$

Parc, Alcatel, Cisco are working on Information Centric Routers operating at 10Gbps.

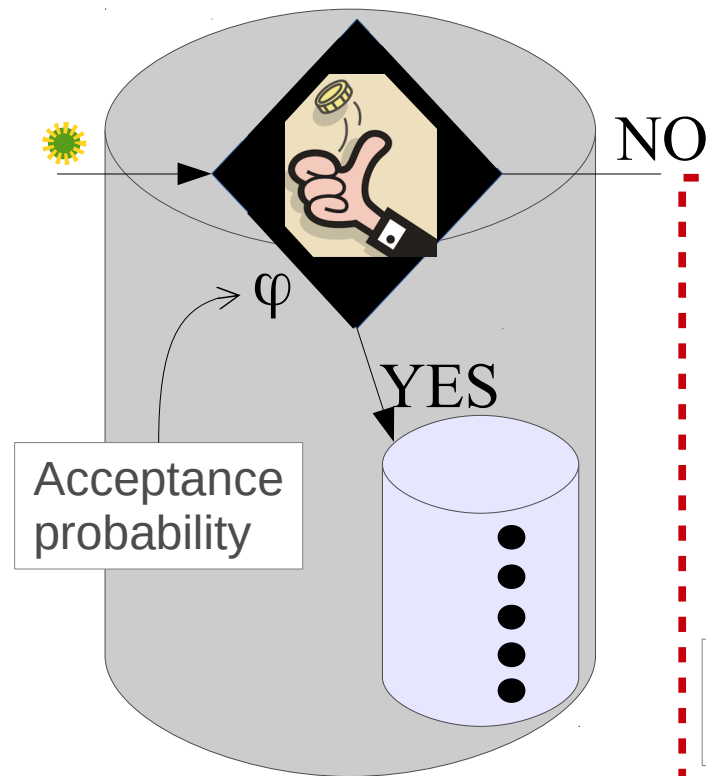

Can we implement a cost-aware cache strategy?

A. Araldo, D. Rossi, F. Martignon, "Design and Evaluation of Cost-aware Information Centric Routers", in ACM SIGCOMM Conference on Information-Centric Networking (ICN), Paris, **2014**

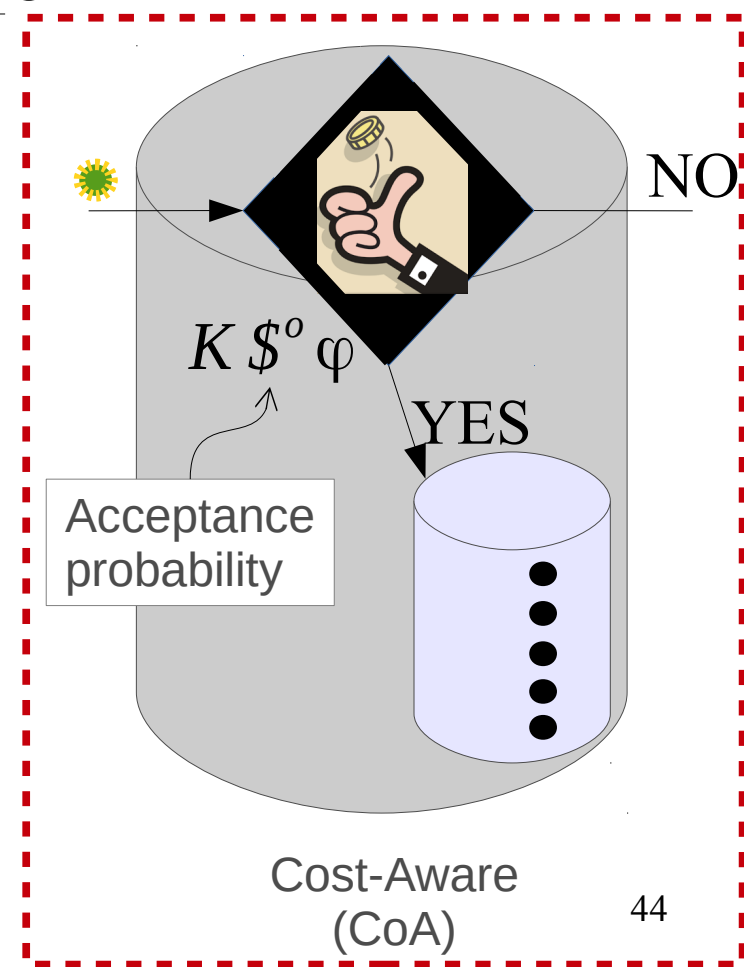

# Decision policies

Always cache

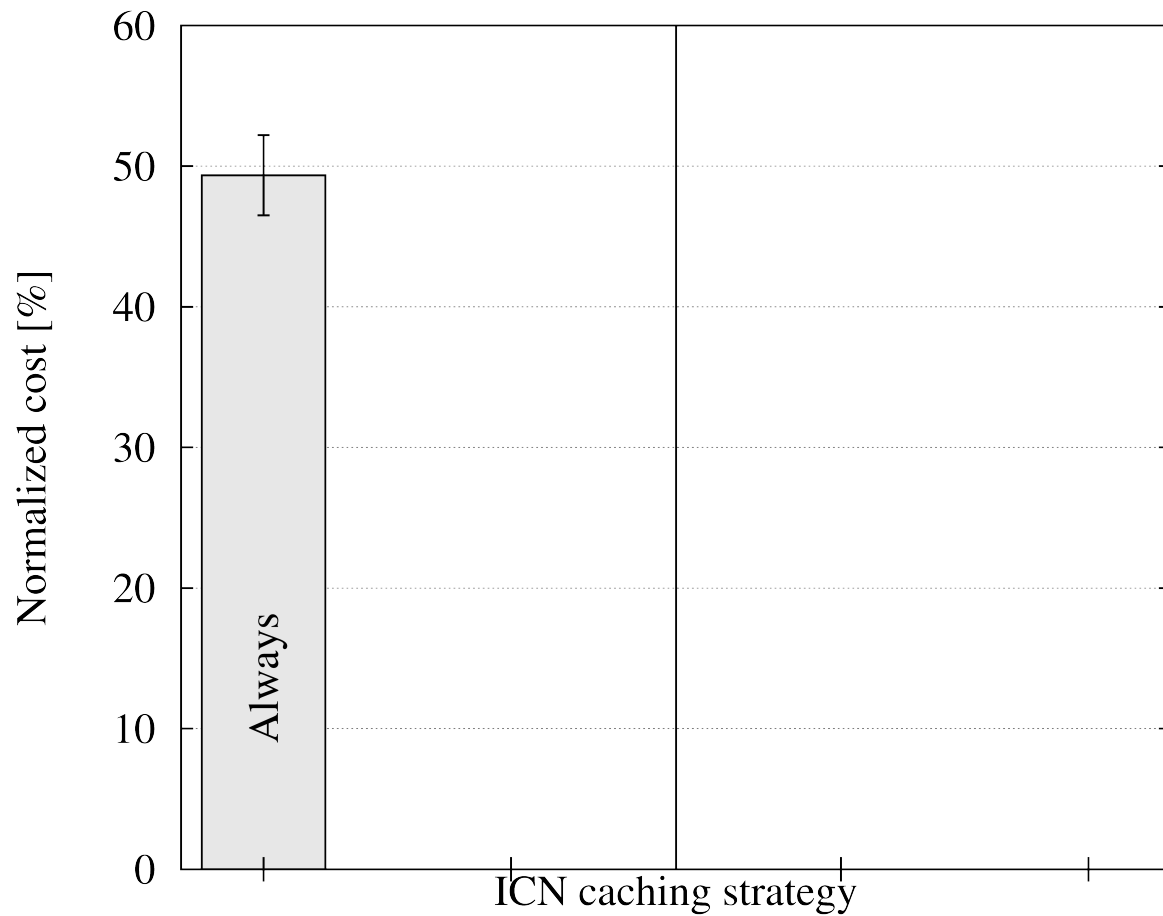

Uniform probabilistic

Cost-Aware (CoA)

# Savings

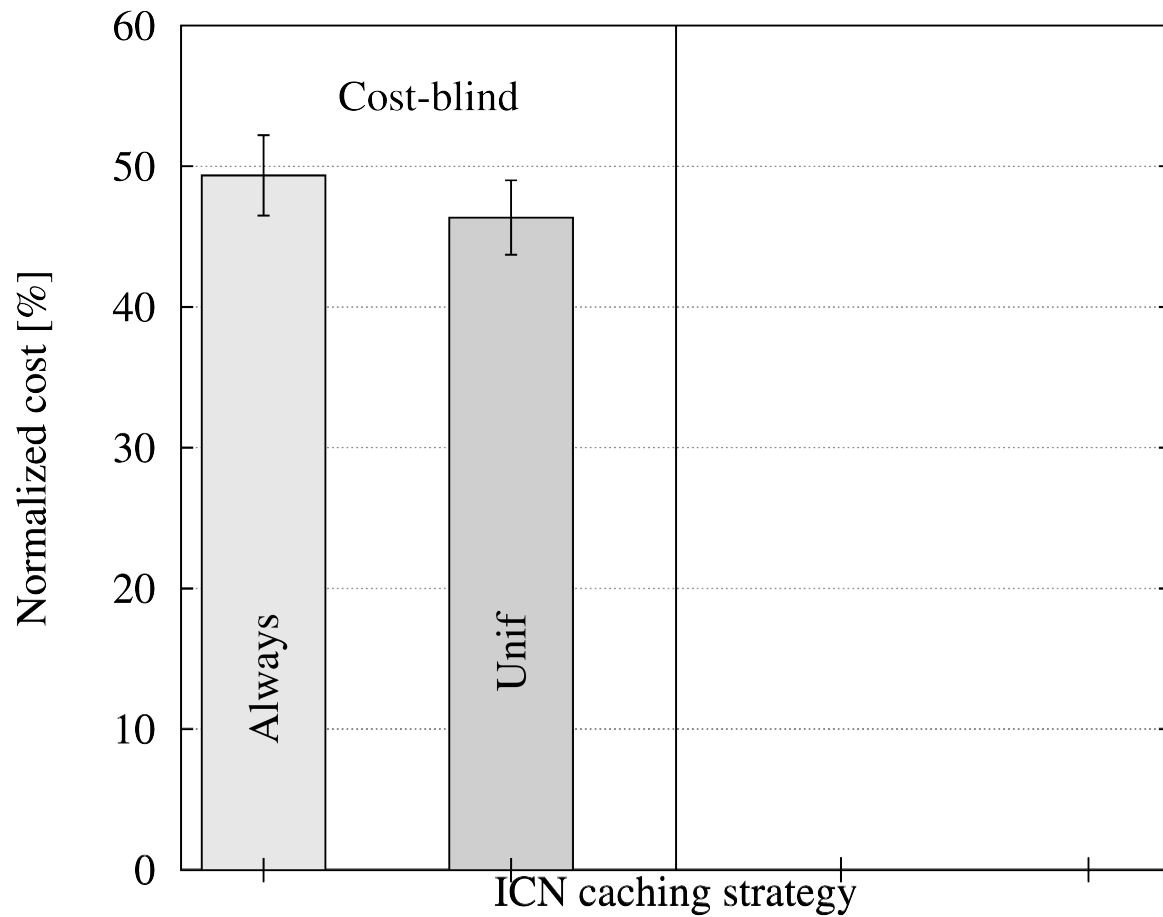

Catalog:  $10^5$  objects  
Cache:  $10^3$  objects  
Zipf exponent: 1  
Prices:  $(\$_1, \$_2, \$_3) = (0, 1, 10)$

# Savings

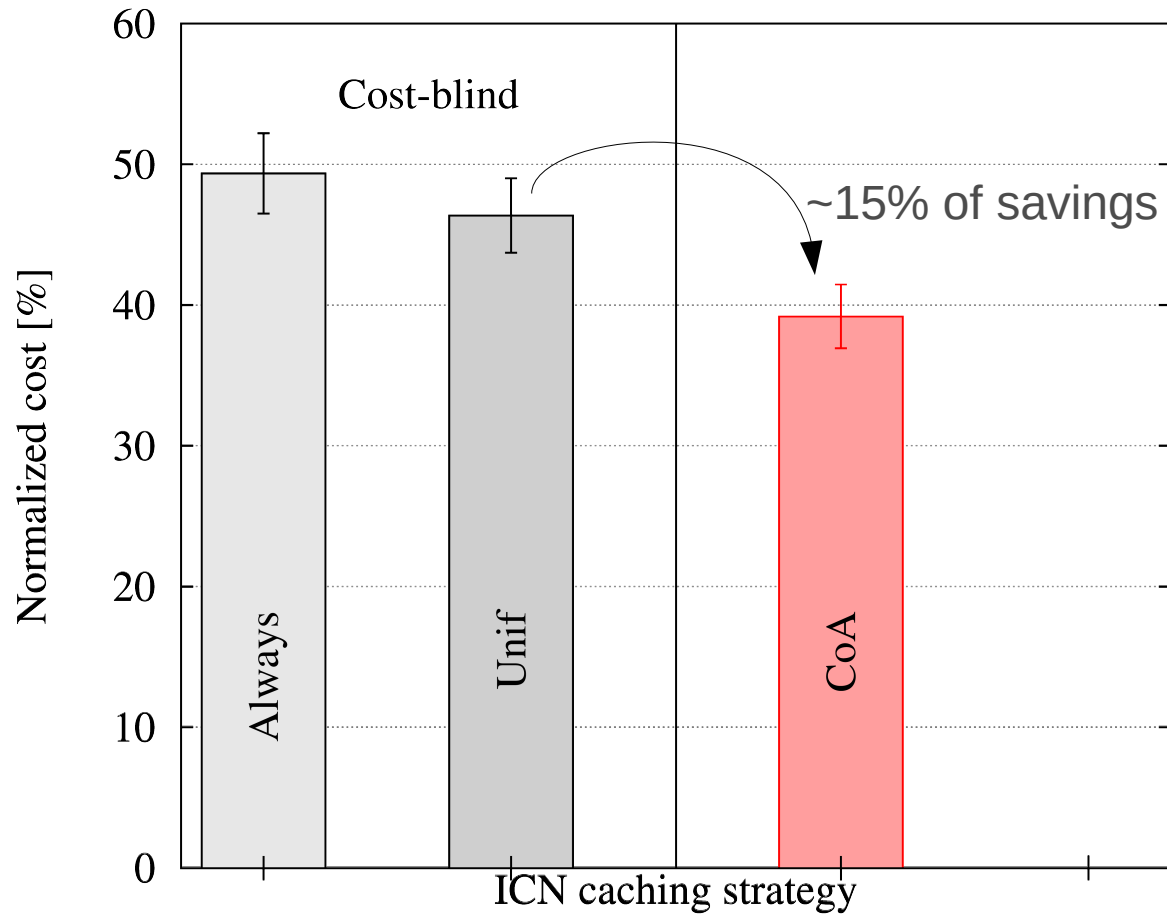

Catalog:  $10^5$  objects  
Cache:  $10^3$  objects  
Zipf exponent: 1  
Prices:  $(\$_1, \$_2, \$_3) = (0, 1, 10)$

# Savings

Catalog:  $10^5$  objects  
Cache:  $10^3$  objects  
Zipf exponent: 1  
Prices:  $(\$_1, \$_2, \$_3) = (0, 1, 10)$

# Savings

Catalog:  $10^5$  objects  
Cache:  $10^3$  objects  
Zipf exponent: 1  
Prices:  $(\$_1, \$_2, \$_3) = (0, 1, 10)$

- Operational cost reduction accumulates over years
- It comes for free (cache deployment cost does not change)

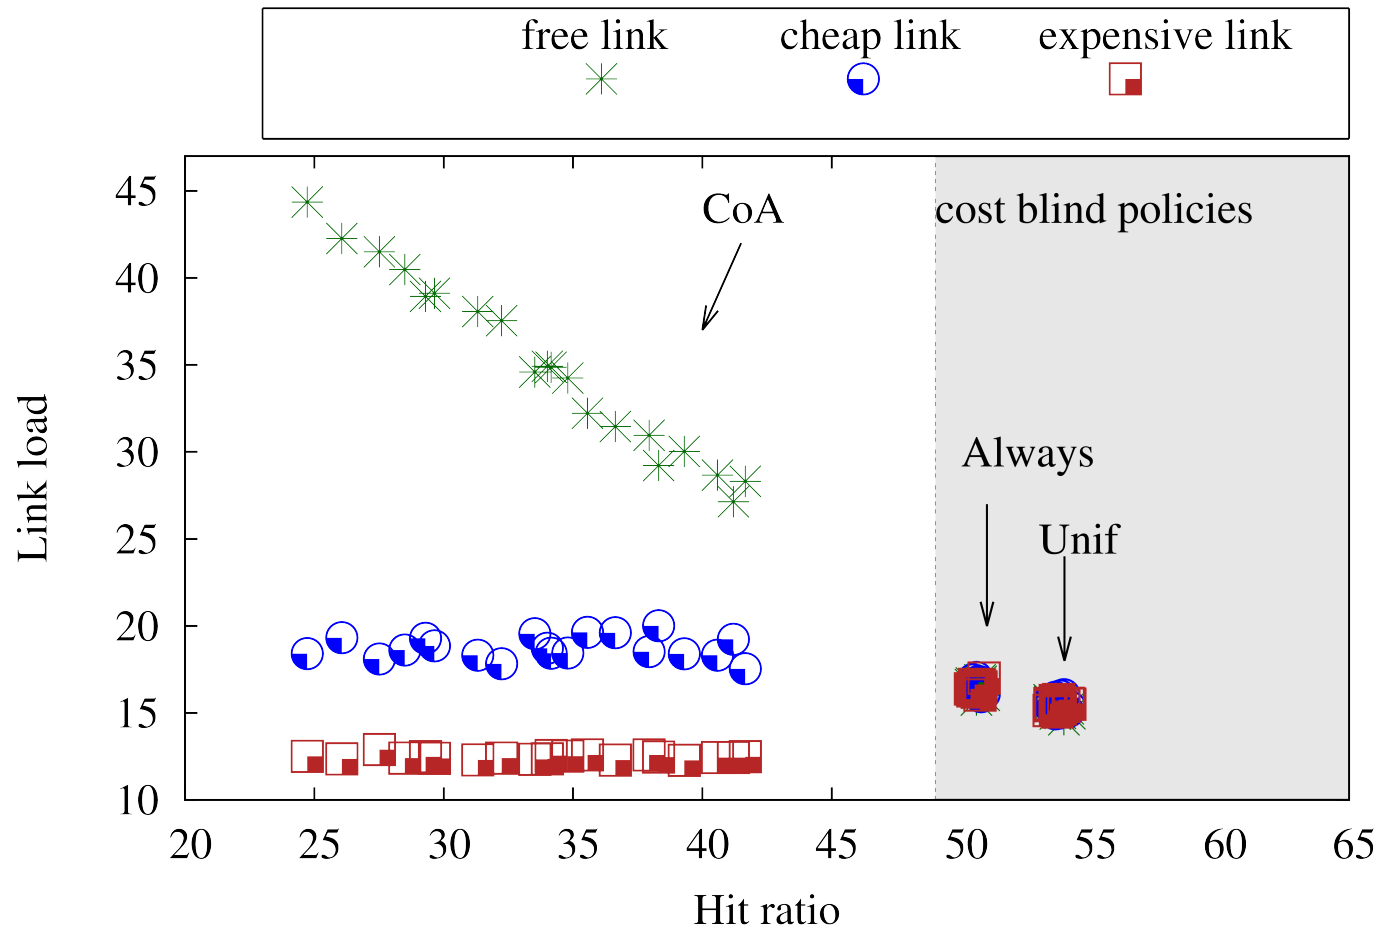

# Conclusion

---

- Our contribution:
  - Optimization model of ISPs operational costs
  - Polynomial time greedy algorithms
  - Design of a Cost-Aware cache strategy
  - Evaluation through simulations
- Take-away message:
  - Do not look at hit ratio when evaluating a cache system
    - Look at your real objective
  - Classic caching is cost-ineffective
  - Cost-aware caching provides consistent savings in theory and in practice

# Link load

$$\text{load}(l) = \frac{\text{downloads from } l}{\text{requests}}$$

- Cost unaware policies distribute load blindly across all links
- On the contrary, CoA effectively **minimizes the load on paid link**
- The paid link load is constant, even when hit ratio decreases

CoA effectively **distributes the additional miss-stream to the free link**
